## Rotated & sorted

Initiate start pointer & reverseval with zero.

Iterate over the length of the array

if arr[i] < arr[i+1] then continue

else increase reverseval.

All the above operation should be inside for loop. At the end of for loop based on reverseval val we can decide if the array is rotated & sorted.

rotateval

| = 1 | > 1 | = 0 |
|---|---|---|
| | return false | return true |

if returnval == 1 then we have to check arr[0] > arr[n-1]

If it is true then return true

else return false

```
if (returnval == 1 && arr[0] >
                        arr[n-1])

  {  return true;

  }
else{
    return false;
    }
```
